System Calls

Programming interface to the services provided by the OS.

System Calls (cont.)

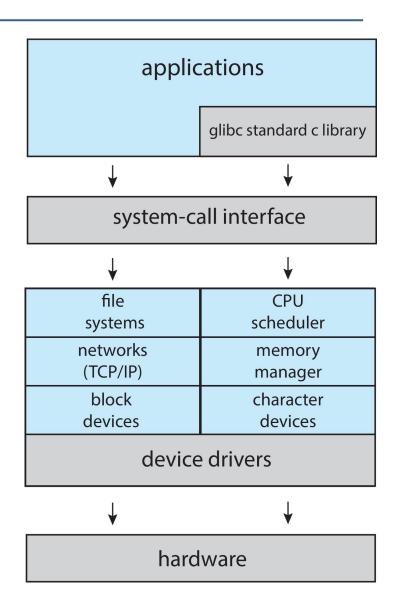

- Typically written in a high-level language (C or C++ or Assembly).
- Mostly accessed by programs via a high-level Application
 Programming Interface (API) rather than direct system call use.

Three most common APIs

- Win32 API for Windows (Win API)
- POSIX API for POSIX-based systems
 - Including virtually all versions of UNIX,
 Linux (*unistd.h*), and Mac OS X
- Java API for the Java virtual machine.

Example of Standard API

EXAMPLE OF STANDARD API

As an example of a standard API, consider the read() function that is available in UNIX and Linux systems. The API for this function is obtained from the man page by invoking the command

man read

on the command line. A description of this API appears below:

```
#include <unistd.h>
ssize_t read(int fd, void *buf, size_t count)

return function parameters
value name
```

Example of Standard API (cont.)

A program that uses the read() function must include the unistd.h header file, as this file defines the ssize_t and size_t data types (among other things). The parameters passed to read() are as follows:

- int fd—the file descriptor to be read
- void *buf —a buffer into which the data will be read
- size_t count—the maximum number of bytes to be read into the buffer

On a successful read, the number of bytes read is returned. A return value of 0 indicates end of file. If an error occurs, read() returns –1.

System Call Implementation

- Typically, a number is associated with each system call
 - System-call interface maintains a table indexed according to these numbers.

The system call interface invokes the intended system call in OS

kernel and returns status of the system call and any return values

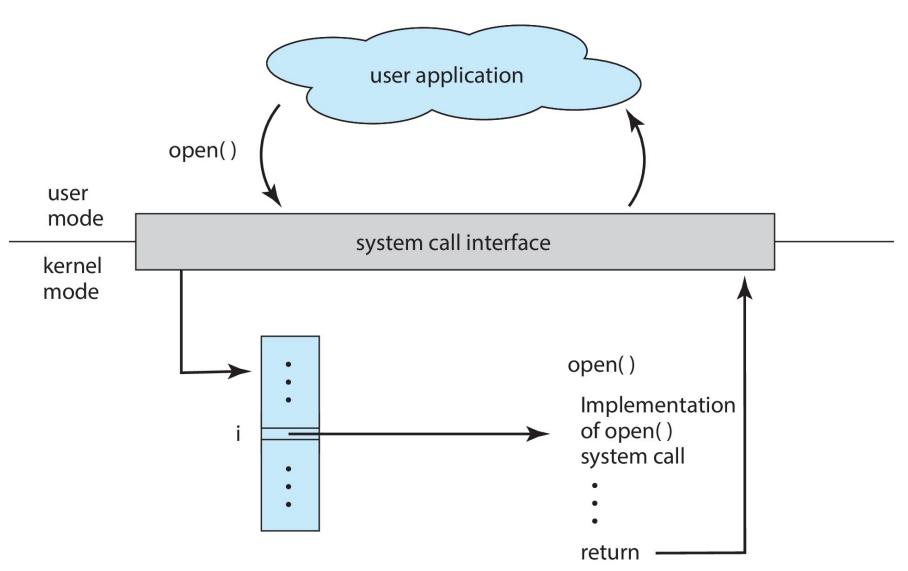

System Call Implementation (cont.)

The caller need know nothing about how the system call is

implemented

- Just needs to obey API and understand what OS will do as a result call.
- Most details of OS interface hidden from programmer by API
 - Managed by run-time support library

API – System Call – OS Relationship

System calls in assembly programs (demo)

- Put the system call number in the EAX register.
- Store the arguments to the system call in the registers EBX, ECX,...
- Call the relevant interrupt (80h).
- The result is usually returned in the EAX register.

Let's see it in practice ©

System Call Parameter Passing

Parameter Passing

- Register
- Register pointer to mem. block
- Stack (Push, Pop)
- Often, more information is required than simply identity of desired system call.
- Exact type and amount of information vary according to OS and call.

System Call Parameter Passing--Methods

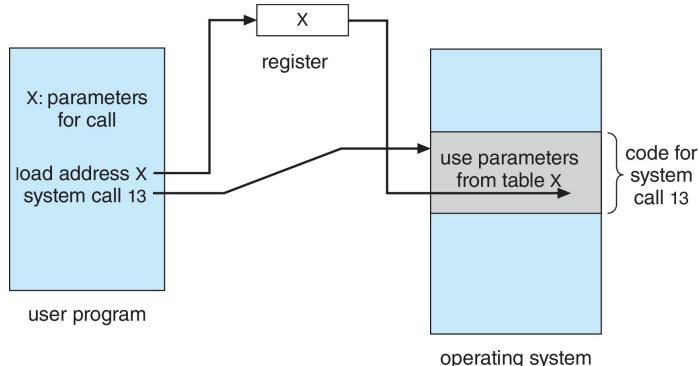

- Simplest: pass the parameters in registers.
 - In some cases, may be more parameters than registers.

System Call Parameter Passing—Methods (cont.)

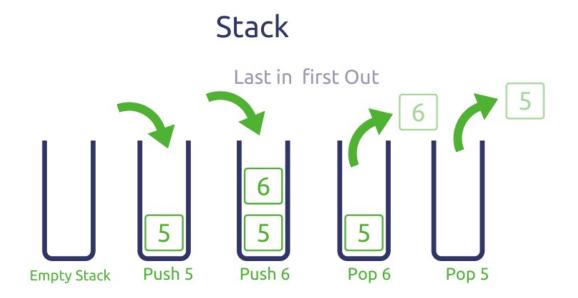

- Parameters stored in a block, or table, in memory, and address of block passed as a parameter in a register.
 - This approach taken by Linux and Solaris.

System Call Parameter Passing—Methods (cont.)

 Parameters placed, or pushed, onto the stack by the program and popped off the stack by the operating system.

System Call Parameter Passing—Methods (cont.)

Methods\features	Is there a limitation on the number of parameters?	Is there a limitation on the length of the parameters?
Register	YES	YES
Register pointer to mem. block	NO	NO
Stack (Push, Pop)	NO	NO

Types of System Calls

Process control

- Create process, terminate process
- •

File management

- create file, delete file
- •

Device management

- request device, release device
- •
- Please study the reference book for more details

Types of System Calls (Cont.)

	Windows	Unix
Process Control	<pre>CreateProcess() ExitProcess() WaitForSingleObject()</pre>	<pre>fork() exit() wait()</pre>
File Manipulation	CreateFile() ReadFile() WriteFile() CloseHandle()	open() read() write() close()
Device Manipulation	SetConsoleMode() ReadConsole() WriteConsole()	ioctl() read() write()
Information Maintenance	<pre>GetCurrentProcessID() SetTimer() Sleep()</pre>	<pre>getpid() alarm() sleep()</pre>
Communication	<pre>CreatePipe() CreateFileMapping() MapViewOfFile()</pre>	<pre>pipe() shm_open() mmap()</pre>
Protection	SetFileSecurity() InitlializeSecurityDescriptor() SetSecurityDescriptorGroup()	<pre>chmod() umask() chown()</pre>

Why Applications are Operating System Specific

Apps compiled on one system usually not executable on other OSs.

- Each OS provides its own unique system calls
 - Own file formats, etc.

- Apps can be multi-operating system
 - Written in interpreted language like Python, Ruby, and interpreter available on multiple OSs.
 - App written in language that includes a VM containing the running app (like Java).
 - Use standard language (like C), compile separately on each operating system to run on each.
